(57) **ABSTRACT**

The embodiments of the present invention disclose a display  
system comprising: a display panel; a backlight module for  
supplying backlight to the display panel; a drive module for  
driving the backlight module to emit light; and a control  
module for controlling the drive module to drive the backlight  
module to emit light, wherein the backlight module com-  
prises first light emitting diodes and second light emitting  
diodes, and a spectral intensity of blue light of light emitted  
by the first light emitting diode is less than a spectral intensity  
of each of red light and green light of the light emitted by the  
first light emitting diode; wherein the drive module comprises  
a first drive unit for driving the first light emitting diodes to  
emit light under the control of the control module, and a  
second drive unit for driving the second light emitting diodes  
to emit light under the control of the control module.

## DISPLAY SYSTEM

### CROSS-REFERENCE TO RELATED APPLICATION

This application claims the benefit of Chinese Patent Application No. 201410307081.X filed on Jun. 30, 2014 in the State Intellectual Property Office of China, the whole disclosure of which is incorporated herein by reference.

### BACKGROUND OF THE INVENTION

#### 1. Field of the Invention

Embodiments of the present invention relate to the field of display, and particularly to a display system.

#### 2. Description of the Related Art

There is a need to decrease a spectral intensity of blue light while a luminance and a chrominance of a picture displayed by a liquid crystal display are ensured.

### SUMMARY OF THE INVENTION

The object of embodiments of the present invention is to provide a display system in order to solve a technical problem that a luminance and a chrominance of a display picture are adversely affected when a spectral intensity of blue light is decreased.

According to embodiments of the present invention, there is provided a display system comprising: a display panel; a backlight module for supplying backlight to the display panel; a drive module for driving the backlight module to emit light; and a control module for controlling the drive module to drive the backlight module to emit light, wherein the backlight module comprises first light emitting diodes and second light emitting diodes, and a spectral intensity of blue light of light emitted by the first light emitting diode is less than a spectral intensity of each of red light and green light of the light emitted by the first light emitting diode; wherein the drive module comprises a first drive unit for driving the first light emitting diodes to emit light under the control of the control module, and a second drive unit for driving the second light emitting diodes to emit light under the control of the control module.

### BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic block diagram showing configuration of a display system according to an embodiment of the present invention;

FIG. 2 is a schematic diagram showing a structure of a backlight source according to an embodiment of the present invention;

FIG. 3a is a schematic diagram of a spectrum of light from an ultraviolet ray-excited light emitting diode according to an embodiment of the present invention;

FIG. 3b is a schematic diagram of a spectrum of light from a blue light-excited light emitting diode according to an embodiment of the present invention;

FIG. 3c is a schematic diagram of a spectrum of light from the backlight source in a wide-gamut mode according to an embodiment of the present invention;

FIG. 4 is a schematic block diagram showing specific configuration of a chrominance adjustment module of a display system according to an embodiment of the present invention; and

# 2

FIG. 5 is a schematic diagram showing a color space or a color reproduction range of the display system according to an embodiment of the present invention.

### DETAILED DESCRIPTION OF THE EMBODIMENTS

A further description of the invention will be made in detail as below with reference to embodiments of the present invention taken in conjunction with the accompanying drawings. The present disclosure may, however, be embodied in many different forms and should not be construed as being limited to the embodiment set forth herein; rather, these embodiments are provided so that the present disclosure will be thorough and complete, and will fully convey the concept of the disclosure to those skilled in the art.

According to a general concept of the present invention, there is provided a display system comprising: a display panel; a backlight module for supplying backlight to the display panel; a drive module for driving the backlight module to emit light; and a control module for controlling the drive module to drive the backlight module to emit light, wherein the backlight module comprises first light emitting diodes and second light emitting diodes, and a spectral intensity of blue light of light emitted by the first light emitting diode is less than a spectral intensity of each of red light and green light of the light emitted by the first light emitting diode; wherein the drive module comprises a first drive unit for driving the first light emitting diodes to emit light under the control of the control module, and a second drive unit for driving the second light emitting diodes to emit light under the control of the control module.

In the display system according to embodiments of the present invention, the first light emitting diodes and the second light emitting diodes are disposed in the backlight module, and the spectral intensity of the blue light of the light emitted by the first light emitting diode is less than the spectral intensity of each of the red light and the green light of the light emitted by the first light emitting diode; accordingly the first drive unit for driving the first light emitting diodes to emit light and the second drive unit for driving the second light emitting diodes to emit light are disposed in the drive module; and the first drive unit and the second drive unit can drive the respective light emitting diodes in the backlight module to emit light under the control of the control module, respectively. In this way, the spectral intensity of the blue light can be decreased according to user's requirements while a luminance and a chrominance of a display picture are ensured.

A further description of the invention will be made in detail as below with reference to embodiments of the present invention taken in conjunction with the accompanying drawings. In the following detailed description, for purposes of explanation, numerous specific details are set forth in order to provide a thorough understanding of the disclosed embodiments. It will be apparent, however, that one or more embodiments may be practiced without these specific details. In other instances, well-known structures and devices are schematically shown in order to simplify the drawing.

According to embodiments of the present invention, there is provided a display system. As shown in FIG. 1, the display system comprises: a display panel **100**; a backlight module **200** for supplying backlight to the display panel **100**; a drive module **300** for driving the backlight module **200** to emit light; and a control module **400** for controlling the drive module **300** to drive the backlight module **200** to emit light.

The backlight module **200** comprises first light emitting diodes **201** and second light emitting diodes **202**, and a spec-

tral intensity of blue light of light emitted by the first light emitting diode **201** is less than a spectral intensity of each of red light and green light of the light emitted by the first light emitting diode **201**.

The drive module **300** comprises a first drive unit **301** for driving the first light emitting diodes **201** to emit light under the control of the control module **400**, and a second drive unit **302** for driving the second light emitting diodes **202** to emit light under the control of the control module **400**.

In the display system according to embodiments of the present invention, the first light emitting diodes **201** and the second light emitting diodes **202** are disposed in the backlight module **200**, and the spectral intensity of the blue light of the light emitted by the first light emitting diode **201** is less than the spectral intensity of each of the red light and the green light of the light emitted by the first light emitting diode **201**. Accordingly, the first drive unit **301** for driving the first light emitting diodes **201** to emit light and the second drive unit **302** for driving the second light emitting diodes **202** to emit light are disposed in the drive module **300**. The first drive unit **301** and the second drive unit **302** can drive the respective light emitting diodes in the backlight module **200** to emit light under the control of the control module, respectively. In this way, the spectral intensity of the blue light can be decreased according to user's requirements while a luminance and a chrominance of a display picture are ensured.

In an exemplary example, the first light emitting diode **201** is an ultraviolet ray-excited light emitting diode, while the second light emitting diode **202** is a blue light-excited light emitting diode. In another exemplary example, a spectral intensity of blue light of light emitted by the second light emitting diode **201** may be greater than a spectral intensity of each of red light and green light of light emitted by the second light emitting diode **201**, or the second light emitting diode may be any other common light emitting diode. The first light emitting diode **201** and the second light emitting diode **202** are light emitting diodes emitting white light.

These modules of the display system will be described in detail as below.

In some embodiments, as shown in FIG. 2, in the display system, the first light emitting diodes **201** and the second light emitting diodes **202** in the backlight module **200** may be disposed in a one-to-one correspondence.

If the first light emitting diode **201** is an ultraviolet ray-excited light emitting diode while the second light emitting diode **202** is a blue light-excited light emitting diode, a spectrum of light from the backlight module when the ultraviolet ray-excited, first light emitting diodes **201** alone emit light is shown in FIG. 3a, while a spectrum of light from the backlight module when the blue light-excited, second light emitting diodes **202** alone emit light is shown in FIG. 3b. It can be seen by comparing FIGS. 3a and 3b that peak values of spectral intensity of light from the backlight module when the first light emitting diodes **201** alone emit light are different from peak values of spectral intensity of light from the backlight module when the second light emitting diodes **202** alone emit light.

In some embodiments, the display system can operate in two display modes, i.e., a wide-gamut mode and a blue-light spectral intensity reduction mode, and switching of the corresponding modes is controlled by the control module **400**. In the wide-color gamut mode, the control module **400** controls the first drive unit **301** to drive the first light emitting diodes **201** to emit light while controlling the second drive unit **302** to drive the second light emitting diodes **202** to emit light.

If the first light emitting diode **201** is an ultraviolet ray-excited light emitting diode while the second light emitting

diode **202** is a blue light-excited light emitting diode, a spectrum of light from the backlight module in the wide-color gamut mode is shown in FIG. 3c.

In the blue-light spectral intensity reduction mode, the control module **400** controls only the first drive unit **301** to drive the first light emitting diodes **201** to emit light. In this case, the second drive unit **302** is in an inactive state.

If the first light emitting diode **201** is an ultraviolet ray-excited light emitting diode while the second light emitting diode **202** is a blue light-excited light emitting diode, a spectrum of light from the backlight module in the blue-light spectral intensity reduction mode is shown in FIG. 3b.

In this way, a user can select different display modes according to his/her requirements, thereby decreasing a spectral intensity of blue light according to user's requirements while a luminance and a chrominance of a display picture are ensured.

In some embodiments, in order to ensure reproducibility of color of a display picture, the display system needs to adjust a gain of a blue signal both in the wide-color gamut display mode and the blue-light spectral intensity reduction display mode. Therefore, as shown in FIG. 1, the display system may further comprise a chrominance adjustment module **500**. The entire picture will have a reduced color temperature and become overred due to the light of which the spectral intensity of the blue light is reduced in the blue-light spectral intensity reduction mode. Therefore, the chrominance adjustment module **500** may be specifically configured to increase a gain of a blue signal of a display image signal under the control of the control module **400** in the blue-light spectral intensity reduction mode. In this way, a blue-light brightness is increased to ensure normal display of color of the picture. Accordingly, the blue light-excited light emitting diodes and the ultraviolet ray-excited light emitting diodes simultaneously emit light in the wide-color gamut display mode. Therefore, the chrominance adjustment module **500** is also configured to decrease the gain of the blue signal of the display image signal under the control of the control module **400** in the wide-color gamut mode. In this way, the spectral intensity of the blue light is decreased while the luminance and the chrominance of the display picture are ensured. As a result, normal display of the color of the picture can be ensured.

In some embodiments, as shown in FIG. 4, the chrominance adjustment module **500** of the display system may specifically comprise:

a hue gain adjustment circuit **501** for performing an adjustment of increasing a gain of a blue signal of a received display image signal under the control of the control module **400** in the blue-light spectral intensity reduction mode; and for performing an adjustment of decreasing the gain of the blue signal of the received display image signal under the control of the control module **400** in the wide-gamut display mode, thereby ensuring normal display of color of a display picture; and

a drive switching adjustment circuit **502** for performing a mode switching between the blue-light spectral intensity reduction mode and the wide-gamut display mode under the control of the control module **400** according to user's requirement, and outputting a display image signal processed by the hue gain adjustment circuit **501**.

Furthermore, as shown in FIG. 4, the chrominance adjustment module **500** of the display system may further comprise:

a histogram characteristic detection circuit **503** for performing a histogram characteristic analysis of the received display image signal to acquire a parameter value of a gray scale and a parameter value of a brightness of the display

5

image signal, and outputting the parameter values to the hue gain adjustment circuit **501**; and

a chrominance histogram transformation circuit **504** for performing a matrix transformation of a received display image signal according to a pixel arrangement of the display panel to obtain a display image signal corresponding to the pixel arrangement, and outputting the display image signal corresponding to the pixel arrangement to the hue gain adjustment circuit **501**.

Specifically, when the chrominance adjustment module **500** of the display system according to the embodiments of the present invention operates, the histogram characteristic detection circuit **503** performs the histogram characteristic analysis of a received display image signal to acquire the parameter value of the gray scale and the parameter value of the brightness of the display image signal, and outputs these parameter values to the hue gain adjustment circuit **501**; while the chrominance histogram transformation circuit **504** performs the matrix transformation of the received display image signal according to a pixel arrangement of the display panel to obtain the display image signal corresponding to the pixel arrangement, and outputs the display image signal corresponding to the pixel arrangement to the hue gain adjustment circuit **501**. The hue gain adjustment circuit **501** adjusts a gain of a blue signal of a received display image signal under the control of the control module **400** and sends the adjusted image signal to the drive switching adjustment circuit **502**. The drive switching adjustment circuit **502** performs the mode switching between the blue-light spectral intensity reduction mode and the wide-color gamut display mode under the control of the control module **400** according to user's requirement, and outputs the display image signal processed by the hue gain adjustment circuit **501**. In this way, the blue signal is adjusted both in the wide-color gamut display mode and the blue-light spectral intensity reduction display mode, thereby ensuring reproducibility of color of a display picture and reducing the blue-light spectral intensity.

In some embodiments, as shown in FIG. 1, the display system may further comprise: a signal receiving module **600**, a format conversion module **700**, a luminance adjustment module **800**, and a signal output module **900**.

The signal receiving module **600** is configured to receive display image signals sent by various external signal sources. Generally, the signal receiving module **600** comprises sub-modules such as a tuner **601**, a motion image decoder **602**, a high-definition multimedia interface **603**, an analogue signal input **604**, and an analog-to-digital three-dimensional conversion device **605**, etc., for specifically performing primary processings, such as tuning, decoding, and analog-to-digital conversion, etc., of the received display image signals, and transmits the processed display image signals to the format conversion module **700**.

The format conversion module **700** is configured to convert the received display image signals sent by the various external signal sources into display image signals with a uniform format and send the display image signals with the uniform format to the luminance adjustment module **800** and the chrominance adjustment module **500**.

The luminance adjustment module **800** is configured to adjust a luminance of the display image signal sent by the format conversion module **700**.

The signal output module **900** is configured to output the display image signal processed by the luminance adjustment module **800** and the chrominance adjustment module **500**.

Specifically, when the display system according to the embodiments of the present invention operates, the signal receiving module **600** receives a display image signal sent by

6

an external signal source and performs primary processings, such as tuning, decoding, and analog-to-digital conversion, etc., of the received display image signal; and the format conversion module **700** converts the display image signal primarily processed by the signal receiving module **600** into a display image signal with the uniform format and transmits the display image signal with the uniform format to the chrominance adjustment module **500** and the luminance adjustment module **800**. The chrominance adjustment module **500** processes the received display image signal under the control of the control module **400**, and the display image signal processed by the chrominance adjustment module **500** and the luminance adjustment module **800** is outputted to the display panel **100** through the signal output module **900**. Meanwhile, the drive module **300** drives the backlight module **200** to emit light under the control of the control module **400**. As a result, it is ensured that the display panel **100** normally displays a picture.

In some embodiments, as shown in FIG. 1, in the display system, the signal receiving module **600**, the format conversion module **700**, the luminance adjustment module **800**, the chrominance adjustment module **500**, the signal output module **900**, the control module **400**, and the drive module **300** may be disposed on a same circuit board. This design facilitates compact design of the circuit board and saves a wiring.

Furthermore, in the display system according to the embodiments of the present invention, the ultraviolet ray-excited first light emitting diodes **201** and the blue light-excited second light emitting diodes **202** in a one-to-one correspondence are disposed in the backlight module **200**, and accordingly the first drive unit **301** for driving the first light emitting diodes **201** to emit light and the second drive unit **302** for driving the second light emitting diodes **202** to emit light are disposed in the drive module **300**. In this way, the spectral intensity of the blue light can be decreased in the wide-color gamut mode under the control of the control module **400**. In other words, the spectral intensity of the blue light is reduced while reproducibility of color of a display picture is ensured.

FIG. 5 shows a color reproduction range of the display system according to the embodiment of the present invention in the wide-color gamut mode. As shown in FIG. 5, a total color reproduction range is represented by a sum of a color reproduction range a1 (of a triangular area) and a color reproduction range a2 (of a triangular area).

In an exemplary example, if the first light emitting diode **201** is an ultraviolet ray-excited light emitting diode while the second light emitting diode **202** is a blue light-excited light emitting diode, the ultraviolet ray-excited light emitting diodes and the blue light-excited light emitting diodes are simultaneously driven, and a spectrum of the ultraviolet ray-excited light emitting diode is gentle and close to a spectrum of the blue light-excited light emitting diode. In this way, the spectral intensity of the blue light can be reduced. In the wide-color gamut mode, the reproducibility of color is ensured while the blue-light spectral intensity is decreased.

In the display system according to the embodiments of the present invention, the first light emitting diodes and the second light emitting diodes are disposed in the backlight module, and the spectral intensity of the blue light of the light emitted by the first light emitting diode is less than the spectral intensity of each of the red light and the green light of the light emitted by the first light emitting diode; accordingly the first drive unit for driving the first light emitting diodes to emit light and the second drive unit for driving the second light emitting diodes to emit light are disposed in the drive module; and the first drive unit and the second drive unit can drive the

7

respective light emitting diodes in the backlight module to emit light under the control of the control module, respectively. In this way, the spectral intensity of the blue light can be decreased according to user's requirements while a luminance and a chrominance of a display picture are ensured.

While the blocks and/or elements are illustrated in the drawings, the drawings are provided only for description of the embodiments of the present invention and an actual connectional and/or positional relationship among components of the display system according to the embodiments is not limited to those illustrated in the drawings.

The above embodiments are only used to explain the present invention, and should not be construed to limit the present invention. It will be understood by those skilled in the art that various changes and modifications may be made therein without departing from the spirit of the present invention, the scope of which is defined in the appended claims and their equivalents.

The invention claimed is:

1. A display system, comprising:

a display panel;

a backlight module for supplying backlight to the display panel;

a drive module for driving the backlight module to emit light; and

a control module for controlling the drive module to drive the backlight module to emit light,

wherein the backlight module comprises first light emitting diodes and second light emitting diodes, and a spectral intensity of blue light of light emitted by the first light

8

emitting diodes is lower than a spectral intensity of each of red light and green light of the light emitted by the first light emitting diodes; and

wherein the drive module comprises:

a first drive unit for driving the first light emitting diodes to emit light under the control of the control module, and  
a second drive unit for driving the second light emitting diodes to emit light under the control of the control module.

2. The display system of claim 1, wherein:

the first light emitting diodes are of an ultraviolet ray-excited light emitting diode, and the second light emitting diodes are of a blue light-excited light emitting diode.

3. The display system of claim 1, wherein:

a spectral intensity of blue light of light emitted by the second light emitting diodes is higher than a spectral intensity of each of red light and green light of the light emitted by the second light emitting diodes.

4. The display system of claim 2, wherein:

a spectral intensity of blue light of light emitted by the second light emitting diodes is higher than a spectral intensity of each of red light and green light of the light emitted by the second light emitting diodes.

5. The display system of claim 1, wherein the control module is configured to in a wide-color gamut display mode, control the first drive unit to drive the first light emitting diodes to emit light while controlling the second drive unit to drive the second light emitting diodes to emit light; and

only control the first drive unit to drive the first light emitting diodes to emit light in a blue-light spectral intensity reduction mode.

6. The display system of claim 5, further comprising:

a chrominance adjustment module for increasing a gain of a blue signal of a display image signal under the control of the control module in the blue-light spectral intensity reduction mode, and for decreasing the gain of the blue signal of the display image signal under the control of the control module in the wide-color gamut mode.

7. The display system of claim 6, wherein:

the chrominance adjustment module comprises:

a hue gain adjustment circuit for performing an adjustment of increasing a gain of a blue signal of a received display image signal under the control of the control module in the blue-light spectral intensity reduction mode, and for performing an adjustment of decreasing the gain of the blue signal of the received display image signal under the control of the control module in the wide-color gamut display mode; and

a drive switching adjustment circuit for performing a mode switching between the blue-light spectral intensity reduction mode and the wide-color gamut display mode under the control of the control module, and outputting a display image signal processed by the hue gain adjustment circuit.

8. The display system of claim 7, wherein:

the chrominance adjustment module further comprises:

a histogram characteristic detection circuit for performing a histogram characteristic analysis of the received display image signal to acquire a parameter value of a gray scale and a parameter value of a brightness of the display image signal, and outputting the parameter values to the hue gain adjustment circuit; and

a chrominance histogram transformation circuit for performing a matrix transformation of the received display image signal according to a pixel arrangement of the display panel to obtain a display image signal corre-

9

sponding to the pixel arrangement, and outputting the display image signal corresponding to the pixel arrangement to the hue gain adjustment circuit.

9. The display system of claim 6, further comprising a signal receiving module, a format conversion module, a luminance adjustment module, and a signal output module, wherein:

the signal receiving module is configured to receive display image signals sent by various external signal sources;

the format conversion module is configured to convert the received display image signals sent by the various external signal sources into display image signals with a uniform format and send the display image signals with the uniform format to the luminance adjustment module and the chrominance adjustment module;

the luminance adjustment module is configured to adjust luminance of the display image signals sent by the format conversion module; and

the signal output module is configured to output the display image signals processed by the luminance adjustment module and the chrominance adjustment module.

10. The display system of claim 7, further comprising a signal receiving module, a format conversion module, a luminance adjustment module, and a signal output module, wherein:

the signal receiving module is configured to receive display image signals sent by various external signal sources;

the format conversion module is configured to convert the received display image signals sent by the various external

10

nal signal sources into display image signals with a uniform format and send the display image signals with the uniform format to the luminance adjustment module and the chrominance adjustment module;

the luminance adjustment module is configured to adjust luminance of the display image signals sent by the format conversion module; and

the signal output module is configured to output the display image signals processed by the luminance adjustment module and the chrominance adjustment module.

11. The display system of claim 9, wherein:

the signal receiving module, the format conversion module, the luminance adjustment module, the chrominance adjustment module, the signal output module, the control module, and the drive module are disposed on the same circuit board.

12. The display system of claim 10, wherein:

the signal receiving module, the format conversion module, the luminance adjustment module, the chrominance adjustment module, the signal output module, the control module, and the drive module are disposed on the same circuit board.

13. The display system of claim 1, wherein:

there is an one-to-one correspondence between the first light emitting diodes and the second light emitting diodes in the backlight module.

\* \* \* \* \*
